

# Exceptional Control Flow: Exceptions and Processes

15-213 / 18-213: Introduction to Computer Systems  
13<sup>th</sup> Lecture, Feb. 25, 2014

## **Instructors:**

Anthony Rowe, Seth Goldstein and Gregory Kesden

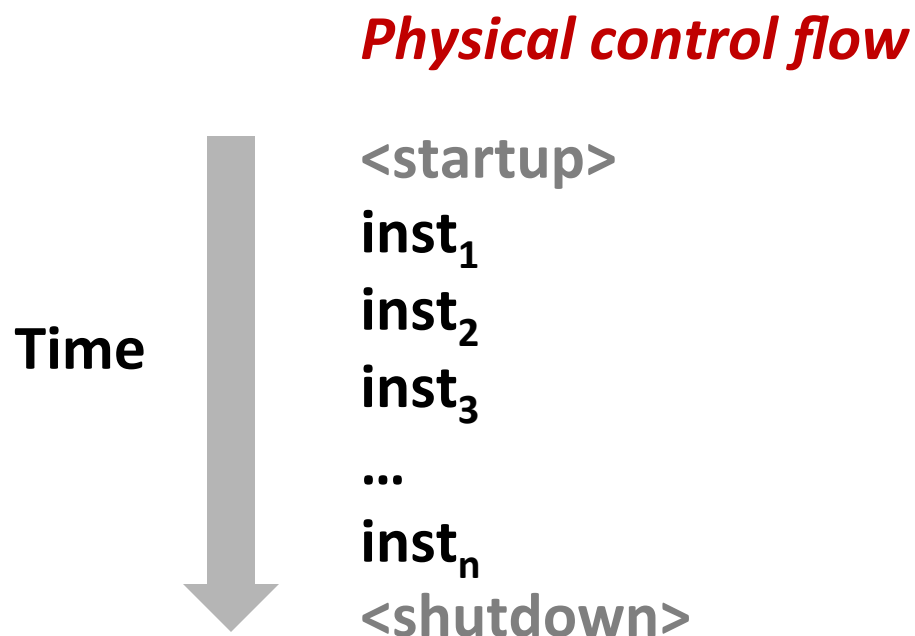

# Today

- **Exceptional Control Flow**
- **Processes**

# Control Flow

## ■ Processors do only one thing:

- From startup to shutdown, a CPU simply reads and executes (interprets) a sequence of instructions, one at a time
- This sequence is the CPU's *control flow* (or *flow of control*)

# Altering the Control Flow

## ■ Up to now: two mechanisms for changing control flow:

- Jumps and branches
- Call and return

Both react to changes in *program state*

## ■ Insufficient for a useful system:

**Difficult to react to changes in *system state***

- data arrives from a disk or a network adapter
- instruction divides by zero
- user hits Ctrl-C at the keyboard
- System timer expires

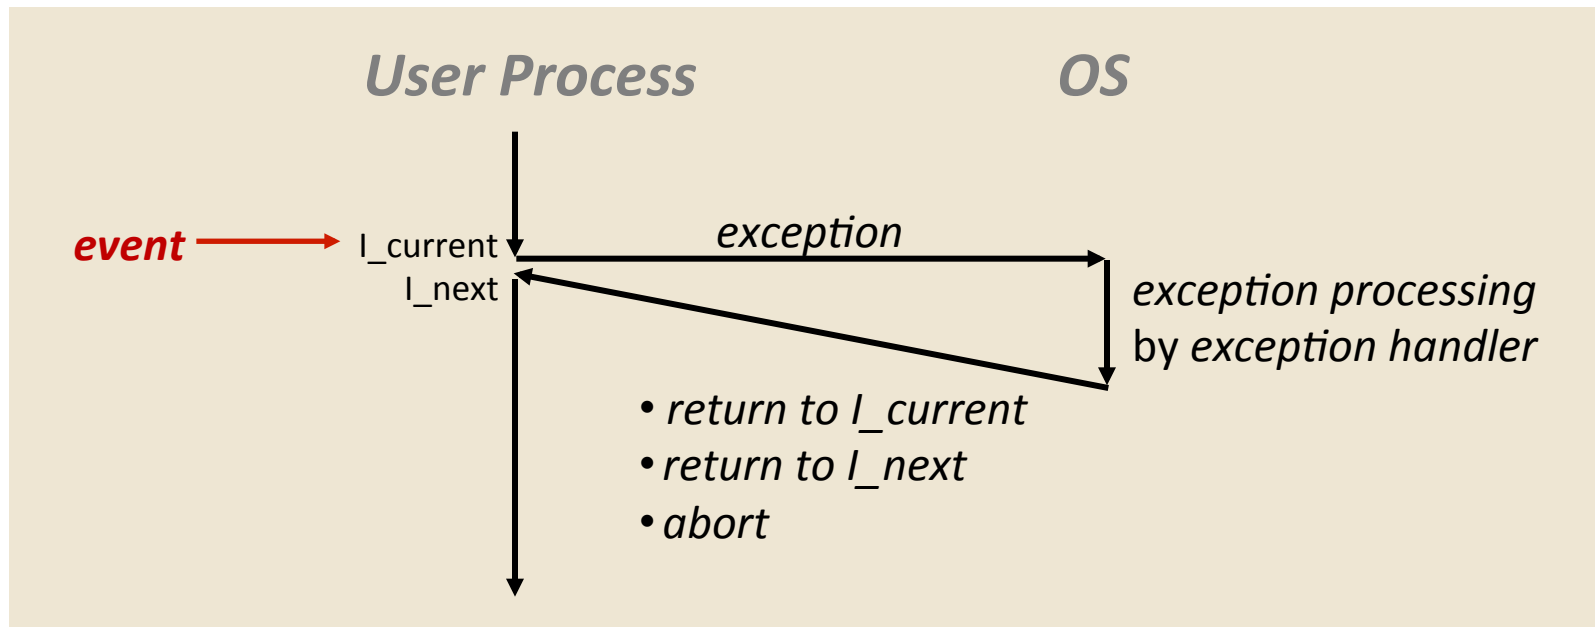

## ■ System needs mechanisms for “exceptional control flow”

# Exceptional Control Flow

- **Exists at all levels of a computer system**
- **Low level mechanisms**
  - Exceptions
    - change in control flow in response to a system event (i.e., change in system state)
  - Combination of hardware and OS software
- **Higher level mechanisms**
  - Process context switch
  - Signals
  - Nonlocal jumps: `setjmp()/longjmp()`
  - Implemented by either:
    - OS software (context switch and signals)
    - C language runtime library (nonlocal jumps)

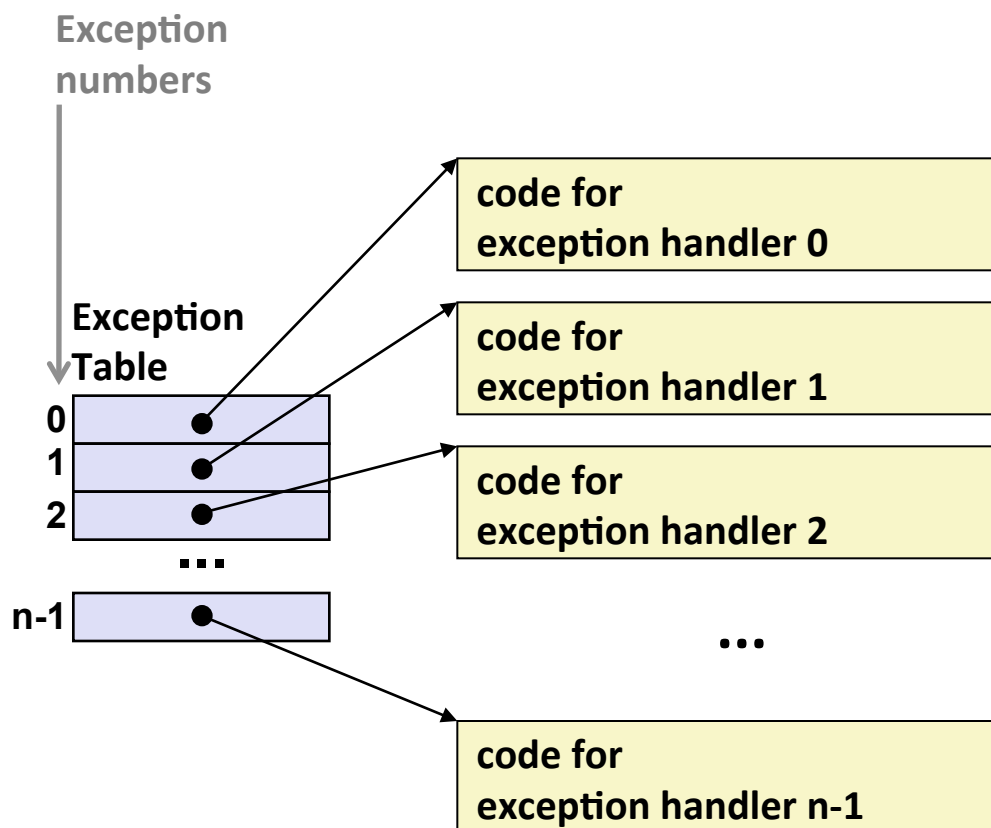

# Exceptions

- An **exception** is a transfer of control to the OS in response to some *event* (i.e., change in processor state)

- **Examples:**  
div by 0, arithmetic overflow, page fault, I/O request completes, Ctrl-C

# Exception Tables

- Each type of event has a unique exception number  $k$
- $k$  = index into exception table (a.k.a. interrupt vector)
- Handler  $k$  is called each time exception  $k$  occurs

# Asynchronous Exceptions (Interrupts)

## ■ Caused by events external to the processor

- Indicated by setting the processor's interrupt pin
- Handler returns to “next” instruction

## ■ Examples:

- I/O interrupts
  - hitting Ctrl-C at the keyboard
  - arrival of a packet from a network
  - arrival of data from a disk
- Hard reset interrupt
  - hitting the reset button
- Soft reset interrupt
  - hitting Ctrl-Alt-Delete on a PC

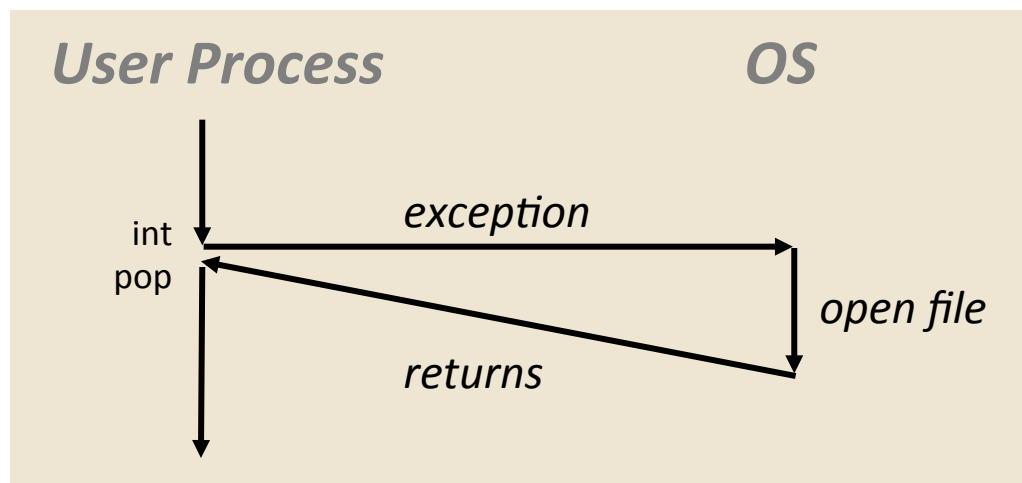

# Synchronous Exceptions

- Caused by events that occur as a result of executing an instruction:
  - **Traps**
    - Intentional
    - Examples: **system calls**, breakpoint traps, special instructions
    - Returns control to “next” instruction
  - **Faults**
    - Unintentional but possibly recoverable
    - Examples: page faults (recoverable), protection faults (unrecoverable), floating point exceptions
    - Either re-executes faulting (“current”) instruction or aborts
  - **Aborts**
    - unintentional and unrecoverable
    - Examples: parity error, machine check
    - Aborts current program

# Trap Example: Opening File

- User calls: `open(filename, options)`
- Function `open` executes system call instruction `int`

```
0804d070 <__libc_open>:  
. . .  
804d082:      cd 80          int    $0x80  
804d084:      5b             pop    %ebx  
. . .
```

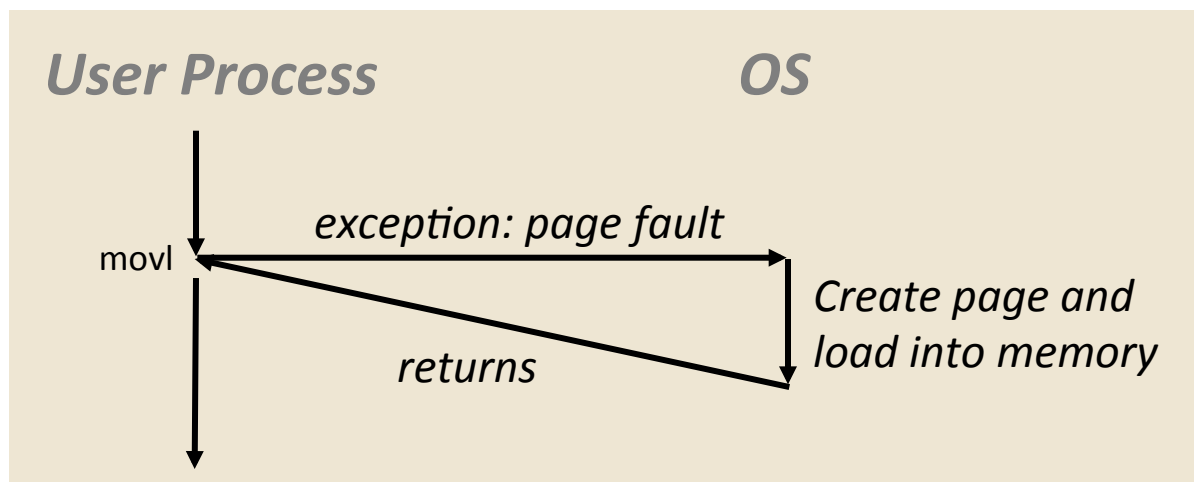

- OS must find or create file, get it ready for reading or writing
- Returns integer file descriptor

# Fault Example: Page Fault

- User writes to memory location
- That portion (page) of user's memory is currently on disk

```
int a[1000];  
main ()  
{  
    a[500] = 13;  
}
```

80483b7:	c7 05 10 9d 04 08 0d	movl	\$0xd,0x8049d10
----------	----------------------	------	-----------------

- Page handler must load page into physical memory
- Returns to faulting instruction
- Successful on second try

# Fault Example: Invalid Memory Reference

```
int a[1000];  
main ()  
{  
    a[5000] = 13;  
}
```

80483b7: c7 05 60 e3 04 08 0d movl \$0xd,0x804e360

- Page handler detects invalid address
- Sends **SIGSEGV** signal to user process
- User process exits with “segmentation fault”

# Exception Table IA32 (Excerpt)

<i>Exception Number</i>	<i>Description</i>	<i>Exception Class</i>
0	Divide error	Fault
13	General protection fault	Fault
14	Page fault	Fault
18	Machine check	Abort
32-127	OS-defined	Interrupt or trap
128 (0x80)	System call	Trap
129-255	OS-defined	Interrupt or trap

Check Table 6-1:

<http://download.intel.com/design/processor/manuals/253665.pdf>

# Today

- Exceptional Control Flow
- **Processes**

# Processes

- **Definition: A *process* is an instance of a running program.**
  - One of the most profound ideas in computer science
  - Not the same as “program” or “processor”
  
- **Process provides each program with two key abstractions:**
  - Logical control flow
    - Each program seems to have exclusive use of the CPU
  - Private virtual address space
    - Each program seems to have exclusive use of main memory
  
- **How are these Illusions maintained?**
  - Process executions interleaved (multitasking) or run on separate cores
  - Address spaces managed by virtual memory system
    - we’ll talk about this in a couple of weeks

# Concurrent Processes

- Two processes *run concurrently* (are concurrent) if their flows overlap in time
- Otherwise, they are *sequential*
- Examples (running on single core):
  - Concurrent: A & B, A & C
  - Sequential: B & C

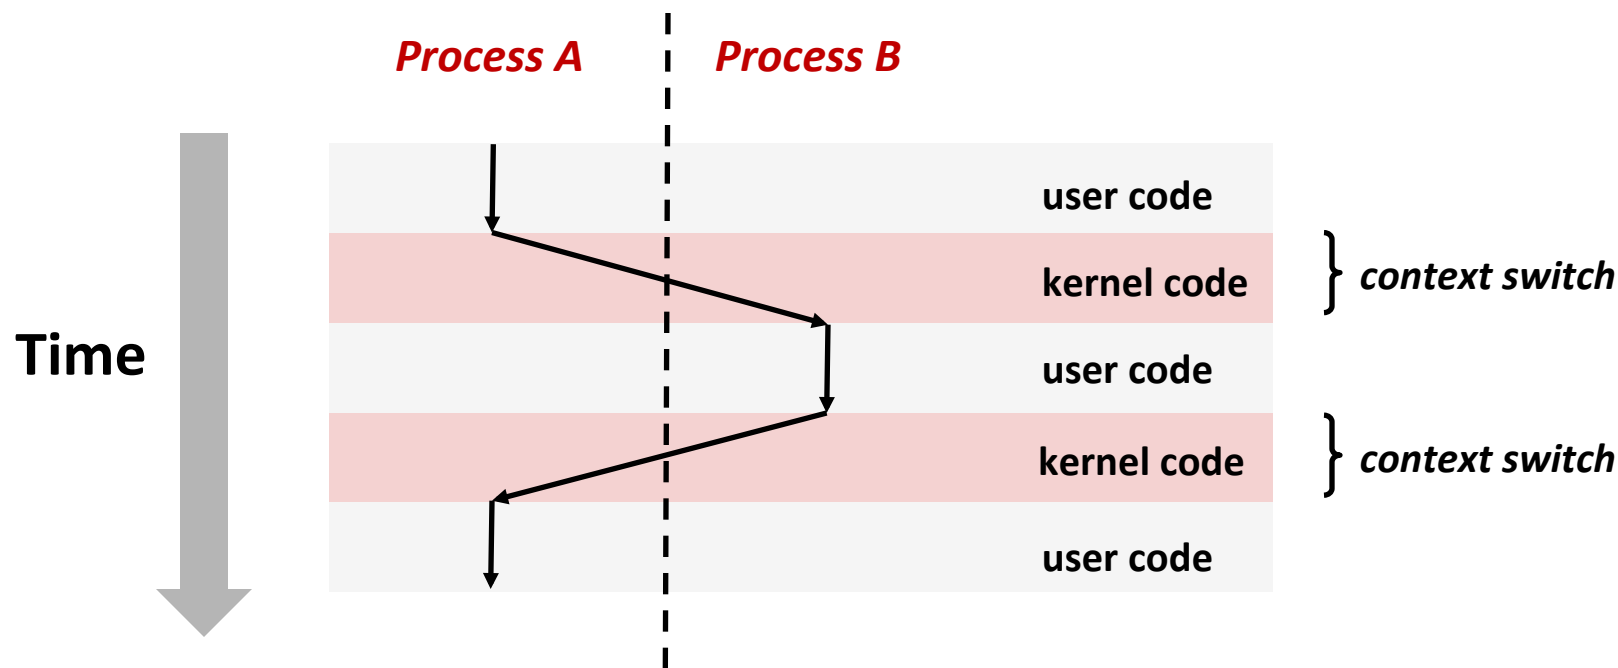

# User View of Concurrent Processes

- Control flows for concurrent processes are physically disjoint in time
- However, we can think of concurrent processes as running in parallel with each other

# Context Switching

- Processes are managed by a shared chunk of OS code called the *kernel*
  - Important: the kernel is not a separate process, but rather runs as part of some user process
- Control flow passes from one process to another via a *context switch*

# fork: Creating New Processes

## ■ `int fork(void)`

- creates a new process (child process) that is identical to the calling process (parent process)
- returns 0 to the child process
- returns child's **pid** (process id) to the parent process

```
pid_t pid = fork();  
if (pid == 0) {  
    printf("hello from child\n");  
} else {  
    printf("hello from parent\n");  
}
```

- Fork is interesting (and often confusing) because it is called *once* but returns *twice*

# Understanding fork

## Process n

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

pid = m

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

## Child Process m

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

pid = 0

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

hello from parent

*Which one is first?*

hello from child

# Fork Example #1

- **Parent and child both run same code**
  - Distinguish parent from child by return value from `fork`
- **Start with same state, but each has private copy**
  - Including shared output file descriptor
  - Relative ordering of their print statements undefined

```
void fork1()
{
    int x = 1;
    pid_t pid = fork();
    if (pid == 0) {
        printf("Child has x = %d\n", ++x);
    } else {
        printf("Parent has x = %d\n", --x);
    }
    printf("Bye from process %d with x = %d\n", getpid(), x);
}
```

# Fork Example #2

## ■ Two consecutive forks

```
void fork2()  
{  
    printf("L0\n");  
    fork();  
    printf("L1\n");  
    fork();  
    printf("Bye\n");  
}
```

# Fork Example #3

## ■ Three consecutive forks

```
void fork3()
{
    printf("L0\n");
    fork();
    printf("L1\n");
    fork();
    printf("L2\n");
    fork();
    printf("Bye\n");
}
```

# Fork Example #4

## ■ Nested forks in parent

```
void fork4()
{
    printf("L0\n");
    if (fork() != 0) {
        printf("L1\n");
        if (fork() != 0) {
            printf("L2\n");
            fork();
        }
    }
    printf("Bye\n");
}
```

# Fork Example #5

## ■ Nested forks in children

```
void fork5()
{
    printf("L0\n");
    if (fork() == 0) {
        printf("L1\n");
        if (fork() == 0) {
            printf("L2\n");
            fork();
        }
    }
    printf("Bye\n");
}
```

# exit: Ending a process

- `void exit(int status)`
  - exits a process
    - Normally return with status 0
  - `atexit()` registers functions to be executed upon exit

```
void cleanup(void) {  
    printf("cleaning up\n");  
}  
  
void fork6() {  
    atexit(cleanup);  
    fork();  
    exit(0);  
}
```

# Zombies

## ■ Idea

- When process terminates, still consumes system resources
  - Various tables maintained by OS
- Called a “zombie”
  - Living corpse, half alive and half dead

## ■ Reaping

- Performed by parent on terminated child (using `wait` or `waitpid`)
- Parent is given exit status information
- Kernel discards process

## ■ What if parent doesn't reap?

- If any parent terminates without reaping a child, then child will be reaped by `init` process (`pid == 1`)
- So, only need explicit reaping in long-running processes
  - e.g., shells and servers

# Zombie Example

```
linux> ./forks 7 &
[1] 6639
Running Parent, PID = 6639
Terminating Child, PID = 6640
linux> ps
```

PID	TTY	TIME	CMD
6585	ttyp9	00:00:00	tcsh
6639	ttyp9	00:00:03	forks
6640	ttyp9	00:00:00	forks <defunct>
6641	ttyp9	00:00:00	ps

```
linux> kill 6639
[1] Terminated
linux> ps
```

PID	TTY	TIME	CMD
6585	ttyp9	00:00:00	tcsh
6642	ttyp9	00:00:00	ps

```
void fork7()
{
    if (fork() == 0) {
        /* Child */
        printf("Terminating Child, PID = %d\n",
            getpid());
        exit(0);
    } else {
        printf("Running Parent, PID = %d\n",
            getpid());
        while (1)
            ; /* Infinite loop */
    }
}
```

- **ps** shows child process as “defunct”
- Killing parent allows child to be reaped by **init**

# Nonterminating Child Example

```
void fork8()
{
    if (fork() == 0) {
        /* Child */
        printf("Running Child, PID = %d\n",
            getpid());
        while (1)
            ; /* Infinite loop */
    } else {
        printf("Terminating Parent, PID = %d\n",
            getpid());
        exit(0);
    }
}
```

```
linux> ./forks 8
Terminating Parent, PID = 6675
Running Child, PID = 6676
linux> ps
  PID TTY          TIME CMD
 6585 ttyp9        00:00:00 tcsh
 6676 ttyp9        00:00:06 forks
 6677 ttyp9        00:00:00 ps
linux> kill 6676
linux> ps
  PID TTY          TIME CMD
 6585 ttyp9        00:00:00 tcsh
 6678 ttyp9        00:00:00 ps
```

- Child process still active even though parent has terminated
- Must kill explicitly, or else will keep running indefinitely

# `wait`: Synchronizing with Children

- Parent reaps child by calling the `wait` function
- `int wait(int *child_status)`
  - suspends current process until one of its children terminates
  - return value is the `pid` of the child process that terminated
  - if `child_status != NULL`, then the object it points to will be set to a status indicating why the child process terminated

# wait: Synchronizing with Children

```
void fork9() {  
    int child_status;  
  
    if (fork() == 0) {  
        printf("HC: hello from child\n");  
    }  
    else {  
        printf("HP: hello from parent\n");  
        wait(&child_status);  
        printf("CT: child has terminated\n");  
    }  
    printf("Bye\n");  
    exit();  
}
```

# wait() Example

- If multiple children completed, will take in arbitrary order
- Can use macros WIFEXITED and WEXITSTATUS to get information about exit status

```
void fork10()  
{  
    pid_t pid[N];  
    int i;  
    int child_status;  
    for (i = 0; i < N; i++)  
        if ((pid[i] = fork()) == 0)  
            exit(100+i); /* Child */  
    for (i = 0; i < N; i++) {  
        pid_t wpid = wait(&child_status);  
        if (WIFEXITED(child_status))  
            printf("Child %d terminated with exit status %d\n",  
                wpid, WEXITSTATUS(child_status));  
        else  
            printf("Child %d terminate abnormally\n", wpid);  
    }  
}
```

# waitpid() : Waiting for a Specific Process

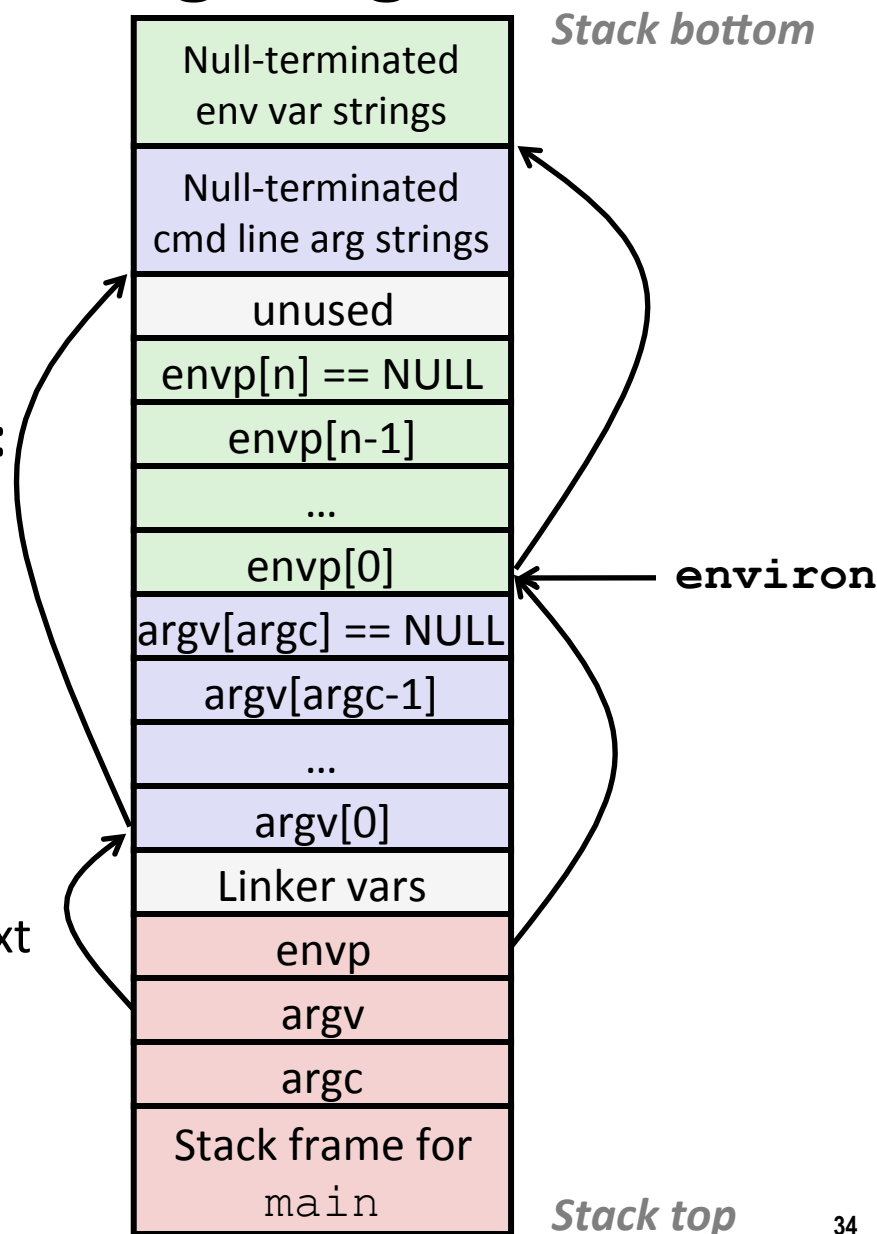

## ■ waitpid(pid, &status, options)

- suspends current process until specific process terminates
- various options (see textbook)

```
void fork11()
{
    pid_t pid[N];
    int i;
    int child_status;
    for (i = 0; i < N; i++)
        if ((pid[i] = fork()) == 0)
            exit(100+i); /* Child */
    for (i = N-1; i >= 0; i--) {
        pid_t wpid = waitpid(pid[i], &child_status, 0);
        if (WIFEXITED(child_status))
            printf("Child %d terminated with exit status %d\n",
                    wpid, WEXITSTATUS(child_status));
        else
            printf("Child %d terminated abnormally\n", wpid);
    }
}
```

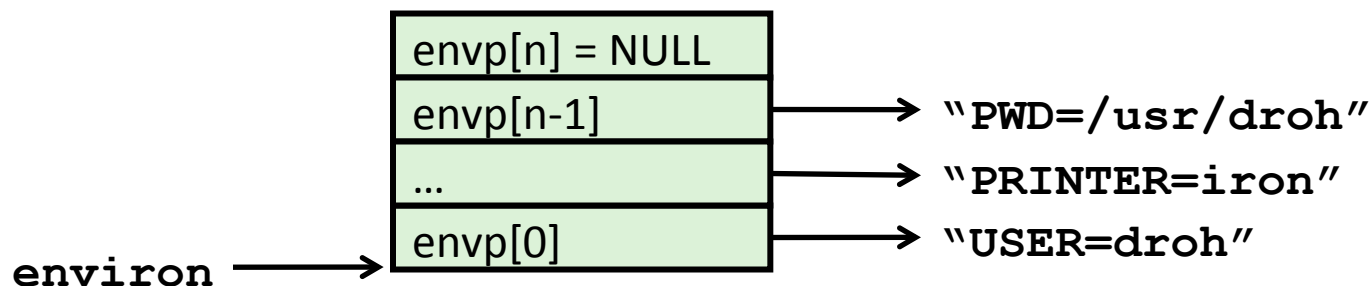

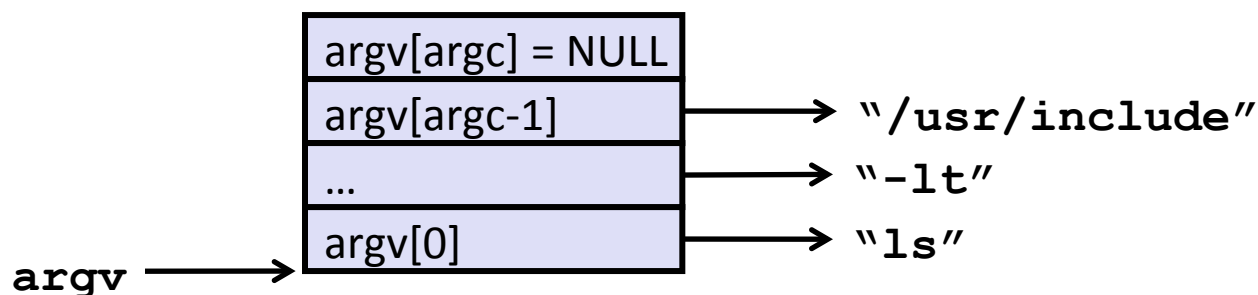

# execve: Loading and Running Programs

- `int execve(`  
`char *filename,`  
`char *argv[],`  
`char *envp[]`  
`)`
- **Loads and runs in current process:**
  - Executable `filename`
  - With argument list `argv`
  - And environment variable list `envp`
- **Does not return (unless error)**
- **Overwrites code, data, and stack**
  - keeps pid, open files and signal context
- **Environment variables:**
  - “name=value” strings
  - `getenv` and `putenv`

# execve Example

```
if ((pid = Fork()) == 0) { /* Child runs user job */  
    if (execve(argv[0], argv, environ) < 0) {  
        printf("%s: Command not found.\n", argv[0]);  
        exit(0);  
    }  
}
```

# Summary

## ■ Exceptions

- Events that require nonstandard control flow
- Generated externally (interrupts) or internally (traps and faults)

## ■ Processes

- At any given time, system has multiple active processes
- Only one can execute at a time on a single core, though
- Each process appears to have total control of processor + private memory space

# Summary (cont.)

## ■ Spawning processes

- Call `fork`
- One call, two returns

## ■ Process completion

- Call `exit`
- One call, no return

## ■ Reaping and waiting for processes

- Call `wait` or `waitpid`

## ■ Loading and running programs

- Call `execve` (or variant)
- One call, (normally) no return
